

Retrieval Practice and Learning

What is the most effective way to learn a subject? Many students focus exclusively on the *encoding* process--- that is, how to get the knowledge into memory in the first place. For example, taking notes is an activity for encoding knowledge.

Retrieval, on the other hand, is the process of reconstructing that knowledge from memory. [Karpicke and Blunt \(http://science.sciencemag.org/content/331/6018/772\)](http://science.sciencemag.org/content/331/6018/772) (2011) demonstrated that *retrieval* is more effective for learning than activities designed to promote effective encoding. They conducted an experiment in which subjects had to learn about sea otters by reading a passage. Subjects were randomly assigned to one of two conditions: some were instructed to create a [concept map \(https://en.wikipedia.org/wiki/Concept_map\)](https://en.wikipedia.org/wiki/Concept_map) as they read the passage, while others were instructed to practice retrieval (i.e., read the passage, recall as much as they could, read the text again, and recall again). The two main measurements they recorded were:

1. each subject's score on a follow-up learning test one week later
2. each subject's *prediction* of how well they would do on that test

In this lab, you will analyze data from a *replication* of Karpicke and Blunt's experiment, conducted by Buttrick *et al.*

- The data file is : data.csv.
- The codebook (explaining what the variables mean) is : codebook.csv.

In [1]:

```
import numpy as np
import pandas as pd

data_df = pd.read_csv("data.csv")
data_df
```

Question 1

Which group felt like they learned more: the subjects who made concept maps or the ones who practiced retrieval? (Or are they about the same?) Make an appropriate visualization and explain what you see.

Hint: Use the variable `PR.2`, which contains the participants' predictions of how well they would do on a test one week later.

In [3]:

```
data_df.groupby("Condition")["PR.2"].mean().plot.bar()
```

Out[3]:

<matplotlib.axes._subplots.AxesSubplot at 0x211783f5348>

The concept maps group learned more on the subject than the retrieval.

Question 2

Which group actually did better on the follow-up learning test one week later? Make an appropriate visualization and explain what you see.

Hint: Don't ask which variable you should use. That is for you to figure out. Read the codebook carefully (consulting the [original paper](http://science.sciencemag.org/content/331/6018/772) (<http://science.sciencemag.org/content/331/6018/772>), if necessary), make an informed decision, and explain your choice.

In [4]:

```
data_df.groupby("Condition")["TS.avg"].mean().plot.bar()
```

Out[4]:

<matplotlib.axes._subplots.AxesSubplot at 0x211786e6708>

The Retrieval group perform better than the concept maps.

Question 3

How good were subjects at predicting how well they would do on the follow-up learning test? Calculate a measure of how well subjects predicted their performance and interpret the value in context. (Optionally, you may want to include a visualization as well.)

In [5]:

```
concept_map_pr2 = data_df[data_df["Condition"] == "Concept"]["PR.2"]  
concept_map_ts_avg = data_df[data_df["Condition"] == "Concept"]["TS.avg"]
```

In [6]:

```
abs(concept_map_pr2 - concept_map_ts_avg).mean()
```

Out[6]:

0.2753846153846154

In [7]:

```
retrieval_pr2 = data_df[data_df["Condition"] == "Retrieval"]["PR.2"]  
retrieval_ts_avg = data_df[data_df["Condition"] == "Retrieval"]["TS.avg"]
```

In [8]:

```
abs(retrieval_pr2 - retrieval_ts_avg).mean()
```

Out[8]:

0.19176470588235295

I took the difference of the concept map prediction response 2 and test score average to find the distance.

Then I calculate the absolute value and the mean of the distance

This will give me the mean of the distance of the concept map prediction response 2 and test score average.

I did the same for retrieval Prediction.

Question 4

This was a completely randomized experiment. This means that the condition that each subject was assigned to should be independent of their gender, age, and any other subject characteristics. Does that seem to be true in this case? Calculate a summary measure and/or make a visualization, and explain what you see.

In [9]:

```
data_df.describe()
```

Out[9]:

	Age	IC.1	IC.2	Comp.1	Comp.2	PR.1	PR.2	MCS.1	MCS.2	MC
count	43.000000	43.0	43.0	43.0	43.0	26.000000	43.000000	26.000000	26.000000	26.0
mean	19.093023	1.0	1.0	1.0	1.0	0.576923	0.645349	0.631731	0.633423	0.6
std	1.108709	0.0	0.0	0.0	0.0	0.503831	0.172797	0.167637	0.163400	0.1

75%	20.000000	1.0	1.0	1.0	1.0	1.000000	0.750000	0.750000	0.779000	0.7
max	22.000000	1.0	1.0	1.0	1.0	1.000000	0.950000	0.917000	0.850000	0.8

8 rows × 11 columns

In [10]:

```
data_df.describe().plot.bar()
```

Out[10]:

```
<matplotlib.axes._subplots.AxesSubplot at 0x211787a1cc8>
```

It looks like the students age group plays a role in the randomized experiment.

The mean of the age group experiment is 19 which can affect the experiment. We can assumed the students are freshmans or sophomore in college/university. In addition, there's a total of 43 students participate. Not a lot students participate in the experiment to fully determine the whether the experiment is good or not.

Submission Instructions

Once you are finished, follow these steps:

1. Restart the kernel and re-run this notebook from beginning to end by going to `Kernel > Restart Kernel and Run All Cells`.
2. If this process stops halfway through, that means there was an error. Correct the error and repeat Step 1 until the notebook runs from beginning to end.
3. Double check that there is a number next to each code cell and that these numbers are in order.

Then, submit your lab as follows:

1. Go to `File > Export Notebook As > PDF`.
2. Double check that the entire notebook, from beginning to end, is in this PDF file. (If the notebook is cut off, try first exporting the notebook to HTML and printing to PDF.)
3. Upload the PDF and Notebook (ipynb) to iLearn.
